ABSTRACT

A difference method, which for one choice of weights applied to the differences leads to equally weighted least squares polynomial fits to equally spaced data, is generalized so that the approximation can be obtained in terms of polynomials chosen by the user in the fitting of equally spaced or unequally spaced data.

FOREWORD

Using this method, an investigation was made into the ballistics field with particular emphasis on the preparation of bombing tables. The work was conducted under Task Assignment Number RMMO-42007/2101/F00809001. Credit is due Richard Hageman, Richard Shannon, Gordon Barker, and Mrs. Jane H. Martina for their assistance in the preparation of the tables found in Appendix A and the example in Appendix B.

INTRODUCTION

The technique of using differences in making polynomial fits to discrete data is not new and has been widely discussed in the literature. However, the method described in this report enables the user to apply this method using any form of interpolating polynomial which best suits his purpose. Also, by changing from ordinary differences, which are used in working with equally spaced data, to divided differences, the method can be used for unequally spaced data.

For the convenience of the user Appendix A contains the tabulations of the multipliers, the weights and the summations of weights through the 4th difference for equally spaced data containing from 5 to 30 points. With the modification presented in the text on Page 9 these weights may be adapted for use with unequally spaced data.

EQUALLY SPACED DATA

Exact nth Degree Fit to $n + 1$ Points

Newton, Gauss, and others have given formulas for obtaining an nth degree fit to $n + 1$ equally spaced points (see reference (a)). Such formulas have the advantage of being readily available, but the disadvantage of not giving the result in the form desired for many applications. At the expense of additional computation it is possible to get the interpolating polynomial in the desired form for any application.

Suppose this form for the nth degree polynomial through $n + 1$ points is

$$f_n = A_0 P_0 + A_1 P_1 + A_2 P_2 + \dots + A_n P_n . \quad (1)$$

P_k can be any kth degree polynomial. The argument used in P_k can be the original independent variable, x , or some other argument, say u , which is a linear function of x .

If the $n + 1$ points are substituted in equation (1), $n + 1$ equations in A_0, A_1, \dots, A_n are obtained. Since

$$\begin{aligned} \Delta^n P_j &= 0 \quad \text{for } j < n , \\ \Delta^n f_n &= A_n \Delta^n P_n . \end{aligned} \quad (2)$$

However,

$$\Delta^r P_r = h^r P_r^{(r)} \quad (3)$$

where $P_r^{(r)}$ is the rth derivative of P_r with respect to the argument used, and h is the increment in that argument between successive points. Equation (2) can then be solved for A_n , with

$$A_n = \frac{\Delta^n f_n}{\Delta^n P_n} = \frac{\Delta^n f_n}{h^n P_n^{(n)}} .$$

Then

$$f_{n-1} = f_n - \frac{\Delta^n f_n}{h^n P_n^{(n)}} P_n \quad (4)$$

will be a polynomial of degree $n - 1$.

If the first n values of f_{n-1} are used it is now possible to find

$$A_{n-1} = \frac{\Delta^{n-1} f_{n-1}}{h^{n-1} P_{n-1}^{(n-1)}} . \quad (5)$$

and

$$f_{n-2} = f_{n-1} - \frac{\Delta^{n-1} f_{n-1}}{h^{n-1} P_{n-1}^{(n-1)}} P_{n-1} . \quad (6)$$

will be a polynomial of degree $n - 2$. The first $n - 1$ values of f_{n-2} can be used to find A_{n-2} and so on until all the A 's have been evaluated. The Newton formula uses P_k 's chosen in such a way that P_n vanishes for the n points used in finding A_{n-1} , P_n and P_{n-1} vanish for the $n - 1$ points used in finding A_{n-2} , etc., which is ideal provided the form obtained for f_n is convenient for use. For some purposes it is desirable to have $P_k = x^k$. It is obvious in such a case that the derivatives and integrals may be seen at a glance if necessary.

Another purpose might call for the use of the Tchebychev polynomials on the right hand side of equation (1) if truncation to a lower degree appears desirable. Other uses of f_n will demand other forms of P_k .

Smoothed nth Degree Fit to $n + l + m$ Points

Let it be assumed that the function defined by the $n + l + m$ values is

$$f = f_n + e \quad (7)$$

where f_n is an n th degree polynomial and e is the error of observation or noise. If a satisfactory method for computing $(\bar{\Delta}^k y)$, the mean k th difference, is available and it can be assumed that $(\bar{\Delta}^k e)$ will be sufficiently small for all k , then the approximation of f ,

$$f_n = A_0 P_0 + A_1 P_1 + A_2 P_2 + \dots + A_n P_n ,$$

can be found.

Since e is involved it will be necessary to use $n + l + m$ values in the computation of every mean difference. A_n can be found from

$$(\bar{\Delta}^n f) \approx A_n \bar{\Delta}^n P_n = A_n \left(h^n P_n^{(n)} \right) . \quad (8)$$

Let

$$\hat{f}_n = f = f_n + e$$

$$\hat{f}_{n-1} = \hat{f}_n - A_n P_n = f_{n-1} + e$$

$$\hat{f}_{n-2} = \hat{f}_{n-1} - A_{n-1} P_{n-1} = f_{n-2} + e , \text{ etc.}$$

Then, for each A_k ,

$$A_k = \frac{\left(\overline{\Delta^k f_k} \right)}{\sum w_k} - \frac{\left(\overline{\Delta^k f_k} \right)}{h^k P_k} , \quad (9)$$

Finding Mean Differences

The weighted mean of the first difference of a set of equally spaced y 's can be written

$$(\bar{\Delta}y) = \frac{1}{\sum w} [w_1 w_2 \dots w_r] \begin{bmatrix} -1 & 1 & 0 & 0 & \dots & 0 \\ 0 & -1 & 1 & 0 & \dots & 0 \\ 0 & 0 & -1 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & \dots & -1 & 1 \end{bmatrix} \begin{bmatrix} y_0 \\ y_1 \\ y_2 \\ \vdots \\ \vdots \\ \vdots \\ y_r \end{bmatrix} \quad (10)$$

If equation (10) is written in the expanded form

$$(\bar{\Delta}y) = \frac{1}{\sum w} (m_0 y_0 + m_1 y_1 + m_2 y_2 + \dots + m_r y_r) , \quad (11)$$

and in the form

$$(\bar{\Delta}y) = \frac{1}{\sum w} [0 w_1 w_2 \dots w_r 0] \begin{bmatrix} 1 & 0 & 0 & \dots & 0 \\ -1 & 1 & 0 & \dots & 0 \\ 0 & -1 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & -1 & 1 \\ 0 & 0 & 0 & \dots & 0 & -1 \end{bmatrix} \begin{bmatrix} y_0 \\ y_1 \\ y_2 \\ \vdots \\ \vdots \\ \vdots \\ y_r \end{bmatrix} , \quad (12)$$

comparison of equations (11) and (12) shows that the m's are minus the first differences of the set $\{0w_1w_2w_3\dots w_r0\}$. Given the w's, the m's can be found and given the m's, the w's can be found. All the weighted mean first differences can be found by these formulas.

There are many ways in which the m's (or w's) can be chosen. One method of making the choice is to minimize the maximum absolute value

of $\frac{m_1}{\sum w}$ (see reference (b)). A choice which is more consistent with

$$\sum w$$

practice is to assume the individual errors to be uncorrelated and to have equal variance. With this in mind let the w's be chosen in such a way as to minimize $M = \sum m^2$, holding $W = \sum w$ constant, which will minimize the variance of (\bar{y}) .

Then

$$dM = 2 \left\{ \left[m_0 \frac{\partial m_0}{\partial w_1} + m_1 \frac{\partial m_1}{\partial w_1} + \dots \right] dw_1 + \left[m_0 \frac{\partial m_0}{\partial w_2} + m_1 \frac{\partial m_1}{\partial w_2} + m_2 \frac{\partial m_2}{\partial w_2} + \dots \right] dw_2 + \dots + \left[\dots + m_{r-2} \frac{\partial m_{r-2}}{\partial w_r} + m_{r-1} \frac{\partial m_{r-1}}{\partial w_r} + m_r \frac{\partial m_r}{\partial w_r} \right] dw_r \right\} = 0 , \quad (13)$$

$$dW = dw_1 + dw_2 + \dots + dw_r = 0 . \quad (14)$$

The requirement for a constrained minimum is met if the rank of the matrix of the coefficients of the dw's in equations (13) and (14) is one. Therefore, the coefficients of the dw's in equation (13) are all equal. From equations (11) and (12) each of these coefficients is a constant times a first difference of the m's. The m's, in turn, are minus the first differences of the set

$$\{0w_1w_2\dots w_r0\}$$

so that this set has a constant second difference and the w function is a quadratic with two known zeros.

The weighted mean of the second difference can be written

$$(\overline{\Delta^2 y}) = \frac{1}{\sum w} [00w_1w_2\dots w_{r-1}00] \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & \dots & 0 & c \\ -2 & 1 & 0 & 0 & 0 & \dots & 0 & 0 \\ 1 & -2 & 1 & 0 & 0 & \dots & 0 & 0 \\ 0 & 1 & -2 & 1 & 0 & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \dots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & 0 & \dots & 1 & -2 \\ 0 & 0 & 0 & 0 & 0 & \dots & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & \dots & 0 & 0 \end{bmatrix},$$

or

$$(\overline{\Delta^2 y}) = \frac{1}{\sum w} (m_0y_0 + m_1y_1 + m_2y_2 + \dots + m_r y_r) . \quad (15)$$

The m 's are the second differences of the set

$$\{00w_1w_2\dots w_{r-1}00\}$$

and minimizing $\sum m^2$ with $\sum w$ held constant leads to the requirement that the w function be a fourth degree polynomial with four known zeros.

In finding the mean k th difference, $(\overline{\Delta^k y})$, the m 's will be $(-1)^k$ times the k th difference of the set

$$\{00\dots 0w_1w_2\dots w_{r-k+1}0\dots 00\}$$

having k zeros at each end. The requirement that $\sum m^2$ be a minimum with $\sum w$ held constant leads to a $2k$ th degree polynomial with $2k$ known zeros for the w function.

The i th weight in getting the mean k th difference from $r + 1$ points can thus be written

$$\rho w_i \binom{k-1+i}{k} \binom{r+1-i}{k}, \quad (16)$$

where ρ is some arbitrary constant. The weights given in Table 2 in Appendix A were obtained by using equation (16). It is seen from the equation that for $k = 0$, $\rho w_i \equiv 1$ for all i .

Since the m 's for finding the mean k th difference satisfy a k th degree polynomial and since the $(k+j)$ th difference of a k th degree polynomial is zero for $j > 0$, the m polynomials are orthogonal over an equally spaced set with equal weighting and are identical, except for an arbitrary multiplier, with orthogonal polynomials for equal spacing and equal weighting discussed on pages 287 - 291 of reference (a) and given on pages 375 - 381 of reference (c). The use of equation (16) in finding the mean k th difference thus leads to an equally weighted least squares polynomial fit of equally spaced data for all possible choices of the P_k 's in equation (1).

The results obtained using the w polynomials of equation (16) and the resulting m polynomials for the P_k 's in equation (1) are, of course, very familiar. The use of the w 's to fit in terms of general P_k 's and the modification of the w 's for fitting unequally spaced data are not so familiar. More general methods for choosing the w 's and m 's may well be a rewarding field for further study.

UNEQUALLY SPACED DATA

Exact n th Degree Fit to $n + 1$ Points

The method for equally spaced data may be modified for use with unequally spaced data by using divided differences instead of ordinary differences.

Thus, if

$$f_n = A_0 P_0 + A_1 P_1 + A_2 P_2 + \dots + A_n P_n, \quad (1)$$

$$f[u_0, u_1, \dots, u_n] = A_n P_n[u_0, u_1, \dots, u_n] \quad (17)$$

where

$$f[u_0, u_1, \dots, u_n] = \frac{f(u_0)}{(u_0 - u_1) \dots (u_0 - u_n)}$$

$$+ \frac{f(u_1)}{(u_1 - u_0) \dots (u_1 - u_n)}$$

$$+ \dots$$

$$+ \frac{f(u_n)}{(u_n - u_0) \dots (u_n - u_{n-1})} ,$$

for any positive integer n , is the n th divided difference defined in reference (a).

If

$$P_n(u) = B_0 + B_1u + B_2u^2 + \dots + B_nu^n ,$$

the n th divided difference of $P_n(u)$ is

$$P_n[u_0, u_1, u_2 \dots u_n] = B_n .$$

So that, except for the arithmetic required in the computation of $f[u_0, u_1, u_2, \dots, u_n]$, A_n is easily found from equation (17).

The finding of f_{n-1} , f_{n-2} , ..., and A_{n-1} , A_{n-2} , ... follows a path parallel to that described for equally spaced data.

Smoothed nth Degree Fit to $n + l + m$ Points

Let

$$(\overline{\Delta^k f})$$

be the mean k th divided difference of f . Then equation (9) can be rewritten

$$A_k = \frac{(\overline{\Delta^k f})}{\Delta^k P_k} , \quad (18)$$

and the problem of fitting is then solved if a satisfactory way can be found for finding the mean k th divided difference.

Finding Mean Divided Differences

The mean kth divided difference can be found from

$$(\bar{\Delta}^k f) \left\{ \frac{1}{\sum \omega} [\omega_1 f[u_0, u_1, \dots, u_k] + \omega_2 f[u_1, u_2, \dots, u_{k+1}] + \dots] \right\}. \quad (19)$$

The optimum choice of the ω 's is a more difficult problem than was the choice of the w 's in the case of equally spaced data. A possible choice is to take

$$\omega_1 = (u_k - u_0) w_1$$

$$\omega_2 = (u_{k+1} - u_1) w_2$$

$$\vdots \quad \vdots$$

$$\vdots \quad \vdots$$

$$\omega_1 = (u_{k+i+1} - u_{i+1}) w_1 ,$$

$$\vdots \quad \vdots$$

$$\vdots \quad \vdots$$

the w 's being those chosen for finding the mean kth difference for equally spaced data. For finding the differences when $k = 0$, choose $w_1 = 1$.

This will approach the equally spaced fitting as the intervals become more nearly equal and may be expected to give reasonable results in other cases.

It should be mentioned that the interesting difference relation between the w 's and m 's, and the resulting generation of the m polynomials, for equally spaced data does not hold true for the w 's and m 's used with unequally spaced data involving divided differences.

Given in Appendix B is an example using this divided difference technique in smoothing $y = \sin x$ over a non-constant data interval.

APPENDIX B

APPLICATION OF SMOOTHING METHOD TO
SINE CURVE USING UNEQUALLY SPACED DATA

Given

$$y = \sin x ,$$

with the points unequally spaced over the interval $0 \leq x \leq 1$, use of the divided difference method described in the text yields results tabulated below. First, let

$$y = f_n = A_0 P_0 + A_1 P_1 + A_2 P_2 + \dots + A_n P_n ,$$

where, in this case $n + l + m = 11$, $n = 4$ and $P_k = x^k$. In this example $u = x$.

The weights, w_i , are chosen by the following modification of the weights already calculated for equally spaced data containing 11 points (see Table 2, Appendix A):

$$w_1 = (u_k - u_0) w_1$$

$$w_2 = (u_{k+1} - u_1) w_2$$

$$\begin{matrix} \cdot & \cdot \\ \cdot & \cdot \\ \cdot & \cdot \end{matrix}$$

$$w_i = (u_{k+i+1} - u_{i+1}) w_i ,$$

$$\begin{matrix} \cdot & \cdot \\ \cdot & \cdot \\ \cdot & \cdot \end{matrix}$$

so that we have

i	w				w			
	k=4	k=3	k=2	k=1	k=4	k=3	k=2	k=1
1	6	30	15	5	2.28	9.6	3.15	0.40
2	18	84	36	9	7.56	25.2	8.64	1.17
3	30	140	56	12	12.00	40.6	9.52	1.32
4	35	175	70	14	12.60	50.75	12.60	0.84
5	30	175	75	15	13.20	52.5	17.25	1.80
6	18	140	70	15	7.74	44.8	12.60	1.65
7	6	84	56	14	2.34	26.88	11.76	0.98
8		30	36	12		9.6	9.0	1.68
9			15	9			2.70	0.99
10				5				0.35

Then proceeding with the fit we obtain the results:

x	y	\tilde{P}_3 ($y - A_4x^4$)	\tilde{P}_2 ($\tilde{P}_3 - A_3x^3$)	\tilde{P}_1 ($\tilde{P}_2 - A_2x^2$)	\tilde{P}_0 ($\tilde{P}_1 - A_1x$)
0.00	0.00000	0.00000	0.00000	0.00000	0.00000
0.08	0.07991	0.07991	0.08000	0.07996	0.00002
0.21	0.20846	0.20842	0.21012	0.20986	0.00001
0.32	0.31457	0.31436	0.32038	0.31977	-0.00001
0.38	0.37092	0.37050	0.38058	0.37972	-0.00001
0.50	0.47943	0.47818	0.50115	0.49966	0.00001
0.61	0.57287	0.57011	0.61182	0.60960	0.00003
0.68	0.62879	0.62452	0.68230	0.67954	0.00002
0.82	0.73115	0.72213	0.82344	0.81943	0.00000
0.93	0.80162	0.78670	0.93450	0.92935	0.00000
1.00	0.84147	0.82152	1.00527	0.99931	0.00001

$$A_4 = 0.01995$$

$$A_3 = -0.18375$$

$$A_2 = 0.00596$$

$$A_1 = 0.99930$$

$$A_0 = 0.00001$$

Therefore

$$\sin x \approx 0.00001 + 0.99930 x + 0.00596 x^2 - 0.18375 x^3$$

$$+ 0.01995 x^4, \quad 0 \leq x \leq 1 \text{ radian}.$$

APPENDIX C

NOTE ON INTERPOLATION WITH TCHEBYCHEV POLYNOMIALS

When Tchebychev polynomials are used in equation (1) for the purpose of truncating to a lower degree the u should be chosen so as to make the balanced oscillations of $T(u)$ occur within the region of interest. Thus, if accurate results are desired for $x_1 < x < x_j$, u should be chosen so that

$$u = -1 \quad \text{for } x = x_1 ,$$

and

$$u = 1 \quad \text{for } x = x_j .$$

This is particularly important in the process of inverse interpolation. For example, suppose one is given the following table of values. The problem of finding the solution of $f(x) = 0$ will obviously involve the investigation of a neighborhood near $x = 1.4$.

x	f(x)
1.0	-4.0000
1.2	-2.8224
1.4	-0.2464
1.6	4.1216
1.8	10.7136

Linear interpolation using the points $(1.4, -0.2464)$ and $(1.6, 4.1216)$ gives $x = 1.411$ as an approximate solution of $f(x) = 0$. Assume that the desired solution lies between $x = 1.40$ and $x = 1.42$, and choose the linear transformation connecting x and u so that $u = -1$ for $x = 1.40$ and $u = 1$ for $x = 1.42$.

The following table can then be used for determining the A's in equation (1):

x	u	$T_4(u)$	$T_3(u)$	$T_2(u)$
1.0	-41	22,592,641		
1.2	-21	1,552,321	-36,981	881
1.4	-1	1	-1	1
1.6	19	1,039,681	27,379	721
1.3	39	18,495,361	237,159	

Using these values of Tchebychev polynomials, points on successively lower degree curves, approximating $f(x)$, can be obtained

x	$f(x)$	f_3	$f_2 = f_3 - A_3 T_3$	$f_1 = f_2 - A_2 T_2$
1.0	-4.0000			
1.2	-2.8224	-2.8224	-2.73919275	
1.4	-0.2464	-0.2464	-0.24639775	-0.24753125
1.6	4.1216	4.1216	4.05999725	3.24274375
1.8	10.7136	10.7136		

$$\Delta^4 f = A_4 \Delta^4 T_4, \quad 0.0384 = 30,720,000 A_4$$

$$A_4 = 1.25 \times 10^{-9}$$

Because of the magnitude of A_4 the term $A_4 T_4(u)$ is neglected.

$$\Delta^3 f_3 = A_3 \Delta^3 T_3, \quad 0.432 = 192,000 A_3$$

$$A_3 = 0.00000225$$

$$\Delta^2 f_2 = A_2 \Delta^2 T_2, \quad 1.8136 = 1600 A_2$$

$$A_2 = 0.0011335$$

Linear interpolation with f_1 gives $x = 1.414184$ as an approximate solution of $f(x) = 0$. This can be used as a first approximation for inverse quadratic interpolation in f_2 , and the approximation obtained from f_2 can be used for starting inverse cubic interpolation in f_3 .

In this case

$$f(x) = x^4 + 3x^3 - 2x^2 - 6x$$

and

$$f(x) = 0$$

for

$$x = \sqrt{2} \approx 1.4142$$

so that

$$f_1$$

has given an excellent approximation of the correct solution.

The accuracy of the various approximations for $f(x)$ within the interval $1.40 < x < 1.42$ for direct interpolation can be seen from the A's:

$$|f - f_3| \leq |A_4| = 1.25 \times 10^{-9}$$

$$|f - f_2| \leq |A_4| + |A_3| = 1.25 \times 10^{-9} + 2.25 \times 10^{-6}$$

$$|f - f_1| \leq |A_4| + |A_3| + |A_2| \approx 0.00113575$$
